Overview of *Wireless Location Signatures* Technology

Wireless Location Signatures

- **Mobile phone measures and reports signal strengths of neighbor cell control channels**
 - Reported mobile assisted handover (MAHO) information
 - Aggregated into network measurement reports (NMRs)
- **Every location creates a unique *Wireless Location Signature***
 - Combine signal strength, delay and temporal behavior
- **Components of *Wireless Location Signatures* technology**
 - **Predicted Signature Database (PSD)** provides highly accurate model of wireless radio environment
 - **Location Engine** capitalizes on proprietary statistical algorithms to estimate the location of handsets

Wireless Signatures Components

- **Location Engine**

- Process location estimation requests from network
- Produce the position estimate

- **PSD Manager**

- Automatically update PSD for RF network changes
- Track and alarm PSD and network anomalies

- **PSD Toolkit**

- Provision PSD (GIS data, parameters, etc.)
- Maintain location system accuracy
 - Create or refresh PSD with new drive test data
 - Manage PSD for network changes and anomalies
- Test location system accuracy off-line
 - Batch location estimation processing
 - Produce performance statistics

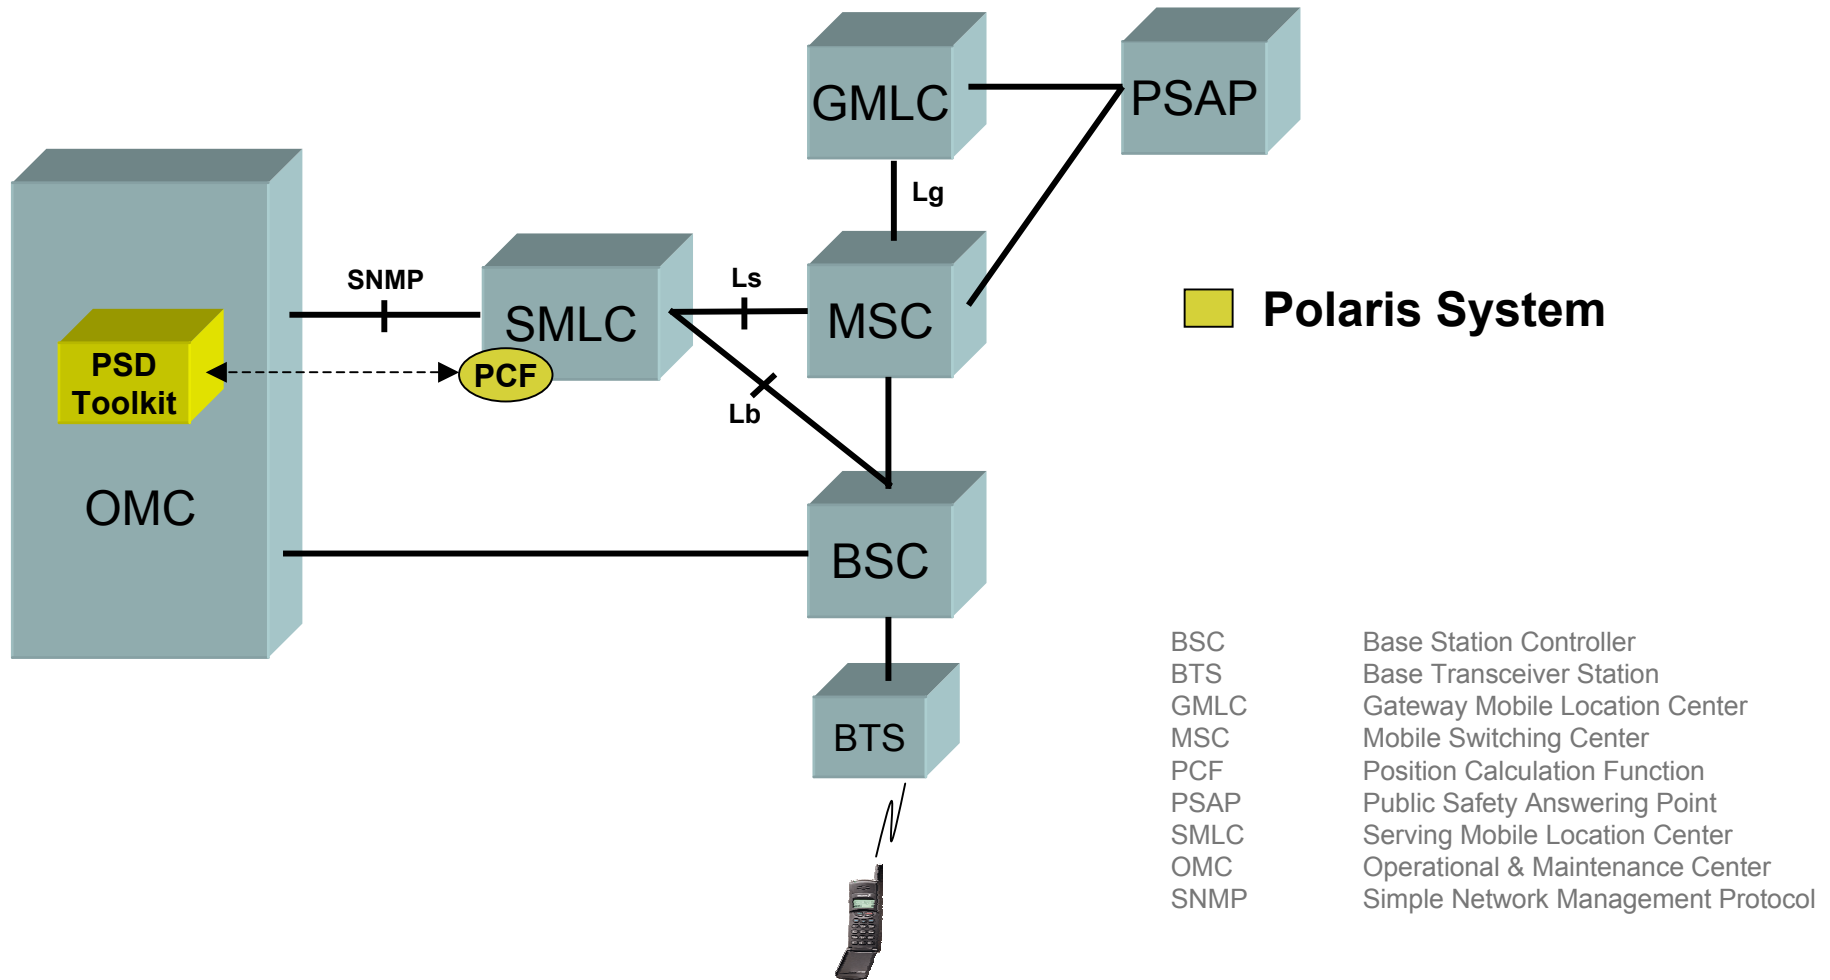

What is a *Wireless Signature*?

Take Advantage of Three Scales of RF Spatial Variation

GSM E-911 Architecture

Wireless Location Signatures **Combined with A-GPS**

Wireless Signatures & A-GPS Combined

- When 0-1 satellites are reported by handset, use *Wireless Signatures* location estimate
- When 2 satellites are reported by handset, create joint *Wireless Signatures & A-GPS* location estimate
- When >2 satellites reported, A-GPS can suffer from bad geometry or multipath, create joint location estimate

Accuracy improvement over *Wireless Signatures* alone depends on collection geometry

- If as shown, improvement could be significant
- If TDOA contours aligned with major axis of *Wireless Signatures* uncertainty, less improvement

Field Trial and OET Test Results

San Jose Testbed: GSM Results

Wireless Location Signatures performance

- Accuracy better than 83 m, 67% of cases
- Accuracy better than 291 m, 95% of cases

San Francisco Testbed: GSM Results

Wireless Location Signatures performance

- Accuracy better than 80 m, 67% of cases
- Accuracy better than 197 m, 95% of cases

Orange UK Field Trial

- **Trial area: Bristol, England**
 - Urban & suburban areas, with 152 cell sectors
 - Urban inter-site average spacing: 290 m
 - Suburban inter-site average spacing: 720 m
 - Total number of measurement reports: ~ 29,000
- **Blind test protocol**
- **Evaluate accuracy for commercial Location Based Services (LBS)**
- **Summary of location accuracy results for combined urban & suburban areas**
 - 65 m for 67% of cases
 - 263 m for 95% of cases

Orange UK Trial: Urban Results

Wireless Location Signatures performance

- Accuracy better than 48 m, 67% of cases
- Accuracy better than 165 m, 95% of cases

Orange UK Trial: Suburban Results

Wireless Location Signatures performance

- Accuracy better than 81 m, 67% of cases
- Accuracy better than 361 m, 95% of cases

Vodafone Field Trials

- **2-phase competitive field trials in 2002 & 2003**
 - 8 - 10 network-based E-CGI location technology companies from around the world
 - **Blind test** protocol used by Vodafone
 - Dortmund, Germany; urban, suburban, & rural areas
 - London, UK; urban & suburban areas
 - Off-line & real-time testing
- **Polaris technology evaluated as having the best performance in both trial phases (>70% over closest competitor)**
- **Polaris system was the only competitor to meet stringent marketing requirements**

Dense Urban -- London

Used only single NMR, rather than block of 50-55 NMRs typically observed in E-911 call interval

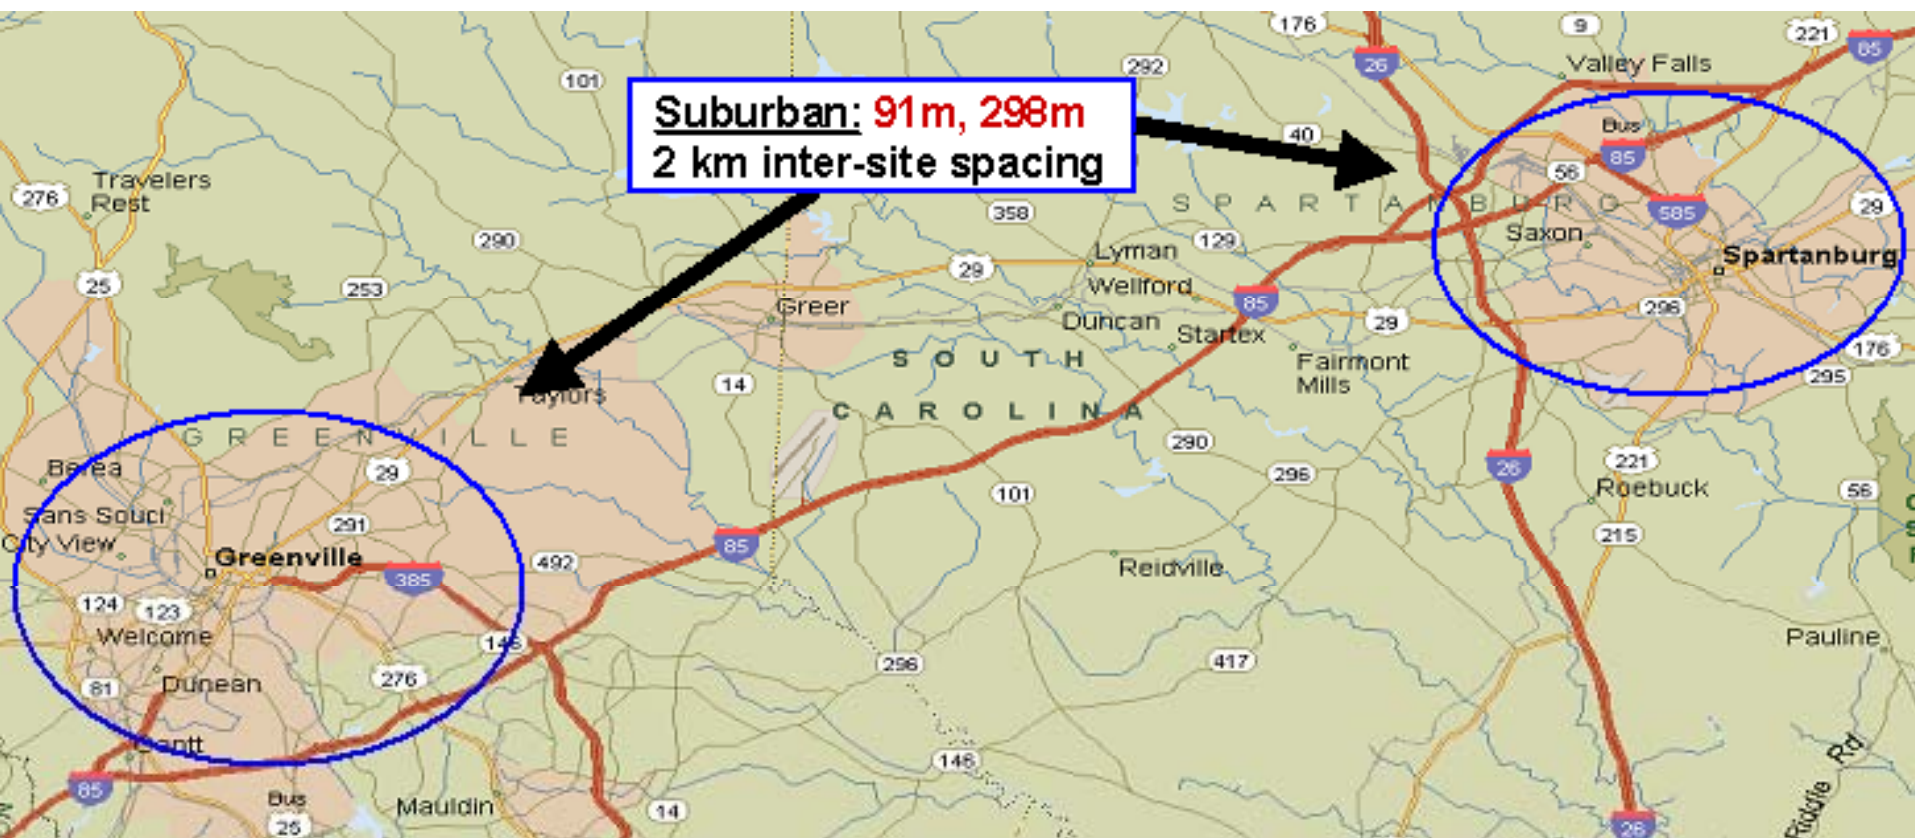

- Accuracy better than 38 m, 67% of cases
- Accuracy better than 88 m, 95% of cases

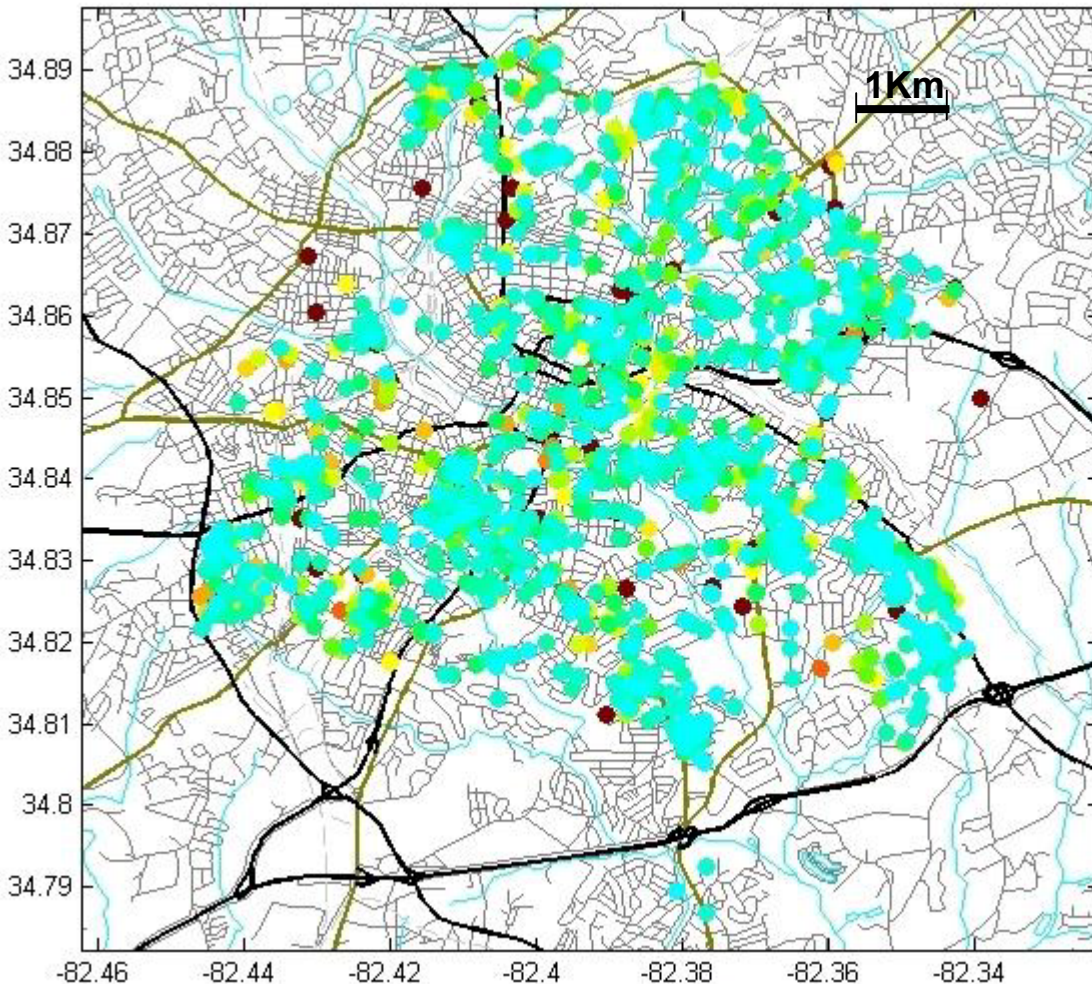

Triton PCS: Live Network OET Tests (IS-136)

- **OET test area**
 - Spartanburg & Greenville, SC
 - Suburban, rural, & highway
 - 60 sites, 150 sectors (cells)
- **OET testing protocol**
 - End-to-end system testing with real-time processing
 - Mix of moving & stationary location fixes
 - Position response time within 30 seconds per location fix
 - MAHO data for position estimation received over E12 interface
 - Ground truth determined from GPS receiver
 - Nokia and Ericsson handsets used
- **Test results show *Wireless Location Signatures* is compliant with FCC's E-911 Phase II accuracy requirements**

Triton PCS: OET Test Summary

Network OET Test Results -- Suburban

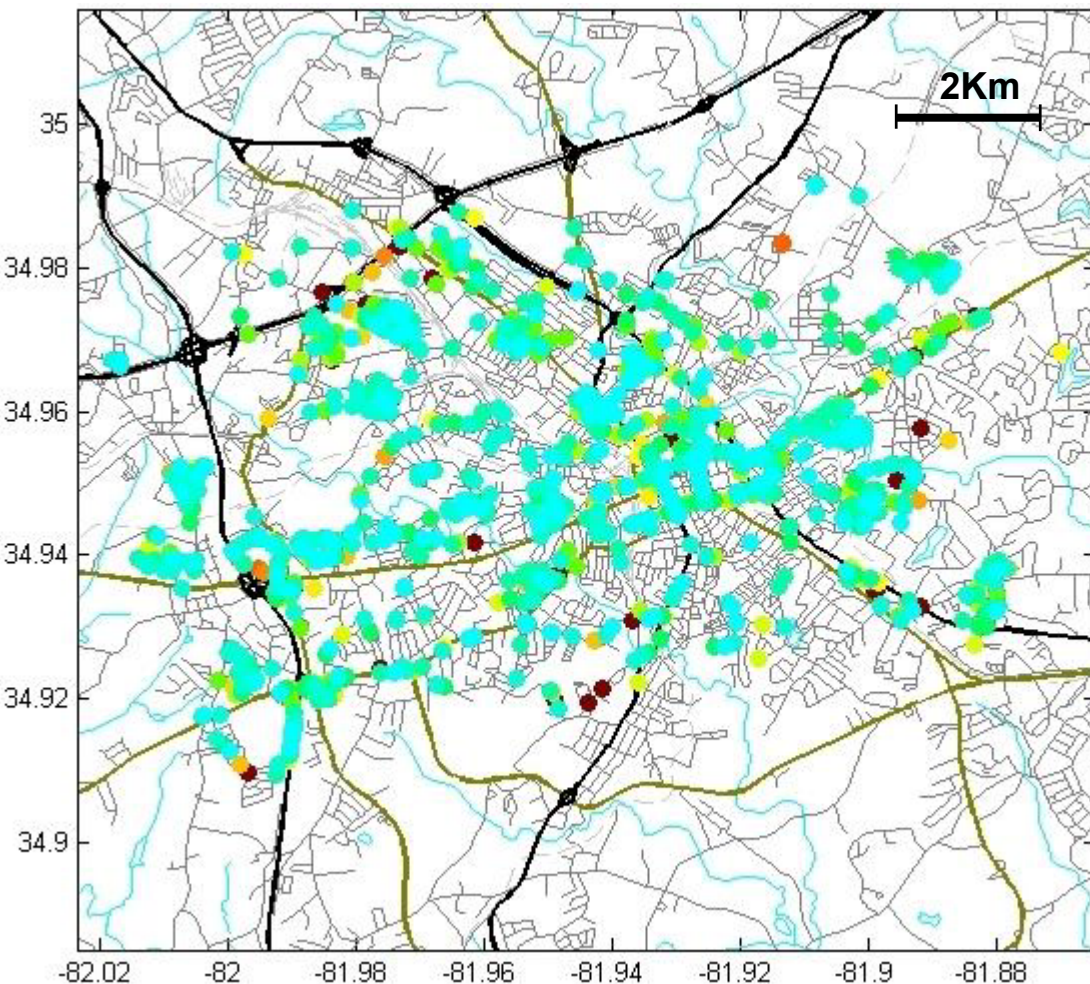

1642 Calls:

67% 86m
95% 294m

Greenville, SC

Network OET Test Results -- Suburban

1311 Calls:

67% 97m
95% 302m

Spartanburg, SC

Accuracy Test Summary

Example Application: Network Optimization

Traffic Density Map

Color coding is number of calls in 100 X 100 m bins during sample hour

Dropped Call Map

Color coding is number of dropped calls in 100 X 100 m bins during sample hour

Conclusions

- **Compliant with E-911 Phase II accuracy requirements for GSM & IS-136**
- **Economical for service providers and public safety community**
- **Immediate coverage for entire installed customer base**
- **High reliability/availability of location system**
- **Deploy as standalone or hybrid system**
- **Support network optimization and location based services**
